LIST OF TABLES

1. Exports of Unworked Coral and shells
2. Imports of Unworked Coral and shells
3. Exports of Worked Coral and shells by weight
4. Exports of Worked Coral and shells by value
5. Imports of Worked Coral and shells by weight
6. Imports of Worked Coral and shells by value
7. Exports of unworked shells
8. Estimated exports of shells
9. US Exports of marine shells
10. US Re-exports of shells
11. Philippines - Exports of 'other shells'
12. Philippines - Exports of 'scrap shell'
- 13a. Exports of shells from Mexico
- 13b. Estimated exports of shells from Mexico
14. Indonesia - Exports of 'other shells'
- 15a. Japan - Exports of shells of shell fishes
- 15b. Japan - Exports of similar substances to coral and shells
and powder and waste
16. Estimated exports from Haiti
17. Solomon Islands - Exports of 'other sea shells'
18. Australia - Exports of shells other than mother-of-pearl
19. Tanzania - Exports of corals, shell, their powder and waste
20. Kenya - Exports of corals, shells, their powder and waste
- 21a. India - Exports of marine shells
- 21b. India - Exports of other corals and shells
22. Malaysia - Domestic Exports of Coral and shells
23. Malaysia - Re-exports
24. Imports of unworked shells
25. Japan - Imports of 'other shells'
26. Japan - Imports of substances similar to coral and shells;
powder and waste
27. France - Imports of unworked shells
28. US - Imports of unworked shells
29. South Korea - Imports of 'other shells'
30. West Germany - Imports of 'other shells'
31. Hong Kong - Imports of Mollusc Shell
32. Spain - Imports of 'other shells'
33. Italy - Imports of unworked coral and shells
34. Australia - Imports of coral and shells
35. Singapore - Imports of coral and shells
36. Malaysia - Imports of coral and shells
37. Kenya - Imports of coral and shells
38. Exports of unworked pearl shell
39. Indonesia - Exports of unworked mother-of-pearl
40. Philippines - Exports of unworked mother-of-pearl
41. Australia - Exports of unworked pearl shell
42. Imports of unworked pearl shell
43. Japan - Imports of Pinctada margaritifera
44. Japan - Imports of Pinctada maxima
45. US - Imports of mother-of-pearl and Trochus
46. Exports of unworked Trochus
47. Indonesia - Exports of 'troca or lola'
48. Solomon Islands - Exports of 'trocas'
49. Philippines - Exports of 'trochea' shell
50. Imports of unworked Trochus
51. Japan - Imports of 'Tectus niloticus'
52. Indonesia - Exports of 'Burgos' or Green snail
53. Solomon Islands - Exports of Green snail
54. Papua New Guinea - Exports of unworked shells

55. South Korea - Imports of Abalone Shell
56. Philippines - Exports of capiz shells
57. India - Trade in cowries and chanks
- 58a. Exports of worked mother-of-pearl by weight
- 58b. Exports of worked mother-of-pearl by value
- 59a. Imports of worked mother-of-pearl by weight
- 59b. Imports of worked mother-of-pearl by value
60. Philippines - Exports of worked shell
61. Taiwan - Exports of worked mother-of-pearl
62. South Korea - Exports of worked mother-of-pearl
63. Japan - Exports of worked mother-of-pearl
- 64a. Hong Kong - Exports of pearl buttons
- 64b. Hong Kong - Re-exports of pearl buttons
- 65a. Japan - Imports of worked mother-of-pearl
- 65b. Japan - Imports of mother-of-pearl for button making
- 66a. West Germany - Imports of worked mother-of-pearl
- 66b. UK - Imports of worked mother-of-pearl
- 66c. France - Imports of worked mother-of-pearl
- 66d. Spain - Imports of worked mother-of-pearl
- 66e. Italy - Imports of worked mother-of-pearl
67. US - Imports of articles of shells
68. US - Imports of shell or pearl buttons
69. Hong Kong - Imports of shell buttons
70. FAO statistics for catches and landings of shells

Figures

1. US exports of marine shells 1960-1978
2. Philippine exports of 'other shells' 1970-1978
3. Japan - Imports of 'other shells' 1970-1979
4. US imports of marine shells 1960-1978
5. US Imports of Articles of shell 1961-1978

INTRODUCTION

One of the main characteristics of the Mollusca, the second largest invertebrate phylum, is the presence in most species of a protective shell into which the animal can withdraw as a defence against predation, dessication or wave action. The shell, secreted by the mantle which is a sheet of skin covering all or part of the body, is composed mainly of calcium carbonate with a small percentage of a protein-like material called conchiolin.

Mollusc shells come in an infinite variety of colours, patterns, shapes and sculpturing, which usually reflect the life style of the species. Gastropods have a single coiled shell with a small aperture. Shells with low spires are most stable and tend to be found in species which move on the vertical surfaces of rocks and vegetation. Long spires are usually dragged along and are found in species living in soft sediments. Many species have developed spines for strengthening, protecting or stabilising the shell; others such as abalones and limpets have become secondarily straightened out and can be clamped tightly to wave-swept rocks. Bivalves have a shell in two parts which fit together tightly to enclose the animal completely. Their shape is less variable than gastropod shells, although burrowing forms tend to have very stream-lined shells.

Many shells have an inner layer of nacre or mother-of-pearl which is made up of tiny blocks of crystalline calcium carbonate arranged in layers. Pearls are formed when sand grains or other particles get lodged between the mantle and the shell, and concentric layers of nacre build up around them. Although pearls can be produced by many species, only certain molluscs

produce commercially valuable ones, such as Pinctada margaritifera and P. mertensi.

Prehistoric man discovered that the soft parts of molluscs provided an easily accessible, nutritive source of food, and since then this group of animals has been exploited heavily. The shell part also gradually came to be valued for a number of reasons, not least of which was its beauty. Shells have been used by many races and cultures as holy objects, currency, jewelry and to decorate clothing and household articles. Calcined shells make the finest lime which is used for pottery glazes and betel chewing, and also for toothpaste and poultry food. Dead shells washed ashore in large quantities or dredged if they occur in large banks may be used for these purposes and include oysters, Meretrix, Arca, Vellorita, Katelaysia (Durve, 1975; Saul, 1974). Building blocks are made from crushed shells and coral, bound together with cement, and where large quantities of empty shells can be dredged they are used in road-making. A detailed history of man's use of shells is provided by Saul (1974).

This report however is concerned mainly with the extensive and escalating trade in tropical shells which are sold as curios and souvenirs to decorate homes, shops, ^{and} restaurants, for jewelry and for other ornamental articles. These come mainly from tropical coral reefs, now recognised as among the most highly productive marine ecosystems. The large scale commercial collection of shells in many areas has led to fears that populations may be being depleted and coral reefs damaged during collection.

Unfortunately foreign trade statistics do not record

tropical shells for the curio trade under a separate tariff heading from those which are dredged or mined for industrial uses. They also do not separate shells collected from the wild from those obtained from shell fish culturing enterprises or from molluscs collected from food. The statistics used in this report are taken from two tariff headings: unworked or raw coral and shells [(05.12 BTN (Brussels Tariff Nomenclature); 291.15 SITC (Standard International Trade Classification))] and worked or carved coral and shells (95.05 BTN; 899.11 SITC). Some countries lump coral and shells together in each section under one tariff heading; other countries separate them under different tariff headings and in the unworked section may have a further heading for "powder and waste of coral and shells; and similar substances". A few countries break their statistics down according to different species or types of shell; for example mother-of-pearl is often recorded separately under the BTN heading 95.02.

In view of the problem of shells not always being recorded separately in trade statistics, an overview of world trade in both corals and shells is given in the following paragraphs. The rest of this report is concerned with the shell trade only, and the coral trade is analysed and discussed in Wells (1980).

Tables 1-6 list all the countries which according to foreign trade statistics were involved in the international coral and shell trade between 1976 and 1978. In these tables figures for corals and shells have been added together for the countries where they were recorded under separate tariff headings. In Table 1

the export figure given by a country was used where this could be obtained; for countries where statistics were not available exports were estimated from figures produced by importing countries. Tables 2-6 list only those countries recording their own imports and exports.

Denmark and the Netherlands recorded the highest exports of unworked coral and shells. These were probably mainly shells for industrial uses, dredged in the North and Baltic Seas, and will not therefore be discussed further in this report. The Philippines and the US were the second major exporters; many of their exports include shells and corals from tropical reefs. Other major exporters include Indonesia, Malaysia, Mexico, Haiti, Australia and a number of Pacific islands. Apart from the European countries, the major exporting countries are in the tropics.

The main importers of unworked coral and shells are the northern European countries, Singapore, Japan, South Korea and the US. Imports into Europe and Singapore are probably mainly shells for industrial purposes (the bulk of Singapore's imports come from Malaysia (Table 35)).

Trade figures for worked coral and shells can be misleading as the items recorded under these tariff headings may include other materials such as wood, metal etc. However it is clear that the Philippines is the major exporter, in terms of both weight and value, followed by Taiwan. Exports from Italy have a high value; this country is traditionally the centre of the cameo and coral carving industry. Japan, West Germany and Thailand are also major exporters of worked coral and shells. The main importers are W. Germany, the US, Japan, Spain and Italy.

Prices of shells are very variable and are not discussed in this report. Abbott(1980) reviews current trends.

UNWORKED SHELLS-EXPORTING COUNTRIES

Countries recording exports of shells are given in Table 7 with a breakdown according to species. Table 8 gives the 'estimated' exports from all countries involved, calculated from figures produced by importing countries, and including all types of shell. This latter table shows that the Netherlands and Denmark are the main exporters (see p.4), and are followed by the US, the Philippines Mexico and Indonesia, which are discussed below in more detail.

USA

Exports of shells from the US increased rapidly in the 1960s reaching a peak in 1966 (Table 9 and Fig. 1). Subsequently exports dropped, averaging about 5,000 tonnes between 1970 and 1978. Between 1960 and 1967 over 50% of exports went to Japan and a large proportion continues to do so; (these are probably freshwater mussels (Abbott,1980) although since 1965 the tariff heading has specified marine shells). Large quantities also went to Canada. Since 1970 exports to South Korea have been increasing; these are probably mainly abalone shells (see p. 14). The US records re-exports of small quantities of marine shells (Table 10), and since 1971 an increasing number have been destined for South Korea. According to Abbott(1980) the US re-exports Haitian shells, especially conches, to the Bahamas. The Bahamas recorded imports of 3 555 conch shells from the US in 1976 and 710 in 1977 (Table 24).

The Philippines

Philippine exports of pearl shells and trochus are discussed later in the section on mother-of-pearl. The main shell exports from the Philippines are recorded under the tariff heading 'other shells' (Table 7) which covers species destined for the curio trade. From 1970 to 1973 exports rose rapidly to a peak (Table 11 and Figure 2) and they have remained fairly high since then. Between 1974 and 1978 the average annual export was 3 451 tonnes. Just under 50% went to the US; about 600 tonnes were exported to Japan annually, and other important countries of destination were Hawai'i, Italy, Spain, the UK, the Netherlands and Hong Kong. A small but variable quantity of scrap shell was exported, most of which went to Taiwan and the US. In 1978 exports were considerably higher than in previous years (Table 12).

Mexico

Shells from Mexico are probably used mainly by the curio trade since they are recorded by importing countries under the category 'other shells'. Actual recorded exports are slightly lower than estimated exports, and were destined mainly for Japan and the US in 1976. (Table 13a). Imports from Mexico into South Korea, Japan and the US increased between 1976 and 1978 (Table 13b).

Indonesia

Most of Indonesia's shell exports are of mother-of-pearl and are discussed later. Exports of 'other shells' reached a peak in 1973 but have declined since then (Table 14). They were destined mainly for Japan, Singapore and Hong Kong.

Japan

Exports of 'shells of shell-fishes' probably includes the shells of cultured pearl oysters. Exports increased six-fold between 1976 and 1979 (Table 15a), the biggest increase being in exports to South Korea. Exports to the US declined. Japan also exported powder and waste of shells and coral to a number of countries including Taiwan, W. Germany, the US and the Netherlands (Table 15b).

Haiti

Between 1976 and 1978 imports from Haiti were recorded by the US, Japan, Spain and Taiwan (Table 16). They were recorded under the tariff heading for 'other shells', and so were probably destined for the curio trade. Estimated annual exports averaged 925 tonnes.

South Korea

Most of South Korea's exports of shells are oysters and are discussed in the mother-of-pearl section. Exports of 'other shells' were recorded in 1977 and 1978 (Table 7), and went to Japan, with a small quantity to Hong Kong (7 300 kg) in 1977. Powder and waste of shell was also destined for Japan (Table 7).

Solomon Islands

Most exports were for the mother-of-pearl trade. A small quantity of 'other shells' was exported between 1976 and 1978 (Table 17).

Australia

Exports of shells other than mother-of-pearl were destined mainly for Hong Kong and South Korea (Table 18).

Other Countries

It has not been possible to carry out detailed analyses for each country.

A number of countries are known to be important exporters of shells but trade statistics do not separate shells from corals, e.g. Kenya, Tanzania, India and Singapore. Between 1974 and 1978 Tanzania recorded higher exports of coral and shells than Kenya (Tables 19 and 20), and most were destined for the US, Europe (especially the UK and Italy) and Japan. Kenya's exports were also destined mainly for the US, Italy and the UK. In 1978 exports from Kenya were the highest since 1974; this may have been in anticipation of the ban on shell exports in 1979 (see discussion). Japan recorded imports of 'other shells' from both countries, imports from Tanzania being higher than those from Kenya (Table 25). The US recorded more imports from Tanzania in the early 1970s but between 1976 and 1978 recorded more from Kenya (Table 28). No countries recorded imports of mother-of-pearl from East Africa.

Indian exports of cowries and chanks (Turbinella pyrum) are described later. Indian exports of marine shells have increased since the beginning of the 1970s and by 1979 reached almost 500 tonnes (Table 21a). Exports to the US increased noticeably, from 40kg in 1969 to nearly 105 tonnes in 1979. Other countries of destination were Hong Kong, Japan and Europe and in 1979 large quantities went to Oman, Bahrein and Kuwait. Foreign trade statistics record exports under the heading 'other corals and shells'. Most were destined for the USA and Europe, and in 1977 large quantities went to Nepal as well (Table 21a). A number of countries recorded imports of shells from India; for example in 1978 Japan

imported Tectus niloticus, Pinctada maxima and other shells from India; South Korea and the US imported shells; and Spain imported mother-of-pearl.

Malaysia recorded huge domestic exports of coral and shells to Singapore (Table 22) and smaller quantities to other countries. The former were probably for building or industrial purposes. Malaysia also re-exports corals and shells (Table 23).

UNWORKED SHELLS-IMPORTING COUNTRIES

Countries recording imports of shells are shown in Table 24. Other major importers are Canada, Italy, the Netherlands, Belgium, Australia and other European countries (see Tables 9 and 11). A number of countries increased their imports of shells between 1976 and 1978 (see below).

Japan

Japanese imports of mother-of-pearl are discussed in the next section. Over three quarters of imports of shells into Japan come under the heading 'other shells' (Table 24), and imports increased nearly two-fold between 1970 and 1979 (Table 25 and Fig. 3). Over 50% came from the US and were presumably freshwater pearly mussels (see p.25). South Korea became an increasingly important supplier throughout the 1970s. Imports from Mexico also increased up to 1978 but in 1979 were half those of previous years. Other major suppliers were the Philippines, Indonesia,

Taiwan and Haiti.

Japan also records imports under the tariff heading 'substances similar to coral and shells; and powder and waste of shells'. These came mainly from the Philippines, South Korea and Taiwan (Table 26) and averaged 402 tonnes a year between 1970 and 1979.

France

French imports came mainly from the Netherlands and Denmark (see p. 4), Turkey and other European countries. In 1976 and 1978 nearly 100 tonnes came from Madagascar (Table 27).

USA

Imports into the US have increased noticeably since the 1960s when average annual imports were 1 483 tonnes (Table 28, Fig 4). The biggest increase has been in imports from Mexico, which became the major supplier in 1977 and 1978, having usually supplied less than 100 tonnes a year in the 1960s. The Philippines was the main source between 1970 and 1976, imports from this country also having increased since the 1960s. Haiti is now the third major supplier; imports from this country increased rapidly at the end of the 1960s but decreased between 1977 and 1978. In the 1960s there were major imports from the Bahamas and Jamaica (Table 28), but although a detailed breakdown of countries of origin is not available for the years 1974-1977, there is evidence that imports from these countries have declined. In 1978 only 3 tonnes came from the Bahamas compared with an annual average of 25 tonnes between 1970 and 1973. Imports from Jamaica totalled 12 tonnes in 1973 compared with an annual average of 323 tonnes between 1960 and 1964.

Imports from Australia have decreased slightly since the

1960s. Imports from Japan have also decreased; these figures parallel the decrease in exports to the US recorded in Japan's trade statistics (Table 15) (although the actual quantities do not agree). No imports were recorded from Taiwan until 1968 but in 1978 this country was the fourth major supplier; highest imports from Taiwan were in 1976. East Africa (i.e. Kenya and Tanzania) was an important supplier most years. Since 1964 imports from the two countries have been recorded separately. Until 1971 higher exports were recorded from Tanzania than from Kenya, but between 1976 and 1978 imports from Kenya were higher.

South Korea

South Korea's imports of oyster, pearl and abalone shell are discussed in the following section. In 1977 and 1978 large quantities of 'other shells' were also recorded (Table 24). Over 90% of these came from Japan, with smaller amounts from Indonesia, the Philippines, India, the US and other countries (Table 29).

West Germany

West Germany imported large quantities of 'other shells' in 1976 and 1977. Most came from Denmark and the Netherlands (Table 30, see p. 4).

Hong Kong

Imports into Hong Kong increased between 1976 and 1978, the main increase being in imports from Australia (Table 31).

Spain

70% of Spanish shell imports came from the Philippines

(Table 32) and 10% from Haiti. Italy, Madagascar and the US were also regular suppliers.

Other Countries

A number of countries which do not separate coral and shells in their foreign trade statistics are also major importers.

Italy imports from a very large number of countries; a detailed breakdown of countries of origin is available for 1976 (Table 33). A large proportion came from Denmark but the main suppliers of tropical corals and shells were Indonesia, the Philippines, the Sudan, the US, Malaysia, Haiti, Australia and New Caledonia. Many of these imports were probably mother-of-pearl and helmet shells or conches for the carving and cameo industry. The US, the Philippines, Indonesia and Australia all recorded exports of shells to Italy (see Tables 9, 11, 14 and 18).

Australian imports of coral and shells increased between 1976 and 1978, and about 50% came from the Philippines. Japan, Taiwan, Mexico and the US were also major suppliers, and in 1978, Haiti and the Solomon Islands as well. (Table 34). The Philippines and the Solomon Islands recorded exports of 'other sea shells' to Australia, and Japan recorded exports of 'shells of shell fishes'.

Singapore imported large quantities of coral and shells from Malaysia (Table 35 and see p.4), and imports also came from the Philippines, New Caledonia, Papua New Guinea and a number of other countries.

Malaysian imports came mainly from Taiwan, the Philippines and Singapore (Table 36). Kenyan imports of coral and shells fluctuated between 1974 and 1978, but came regularly from Somalia. In 1977 and 1978 imports also came from Tanzania (Table 37).

UNWORKED MOTHER-OF-PEARL

Some countries record all types of mother-of-pearl shell under a single heading; others separate 'pearl shell' (i.e. pearl oyster shells) from green snail shells and trochus or top shells (Table 7).

Pearl Shell (Pinctada)

Although this section refers mainly to pearl oyster shells the figures given may include green snail shell and trochus as from some countries it is not known exactly which species are recorded under the tariff heading 'pearl shell'. Between 1976 and 1978 the main exporters were Indonesia, Australia and the Philippines (Table 38). Exports from Indonesia increased markedly between 1970 and 1978 (Table 39), and were destined largely for Japan, Singapore, Hong Kong and South Korea. Exports from the Philippines fluctuated and went mainly to Japan and South Korea (Table 40). Exports from Australia were destined for the US and Europe (Table 41).

The main importers of pearl shell between 1976 and 1978 were Spain, Japan, South Korea and West Germany (Table 42). Many more countries are probably involved but their trade is recorded under the general heading of coral and shells. Japan gives details of imports for two particular species, Pinctada margaritifera and P. maxima. Japanese imports of P. margaritifera came mainly from the Philippines and Indonesia and smaller quantities have come regularly from the Solomon Islands, Papua New Guinea, Fiji and

more recently the Cook Islands (Table 43). Imports of P. maxima have also come mainly from the Philippines and Indonesia, although at the beginning of the 1970s comparatively small quantities were coming from the latter. Australia and Burma have supplied this species to Japan regularly and Papua New Guinea was another important source up until 1973 (Table 44).

Until 1963, the US recorded imports of mother-of-pearl and trochus under a separate tariff heading from other shells. Between 1960 and 1963 most imports came from Australia (c. 60%), and from Japan (20-30%) (Table 45). Since 1963 these imports have been included in 'marine shells'.

Trochus or top shell (Tectus niloticus and Trochidae)

The main exporters of Trochidae shells are Indonesia, Papua New Guinea, the Philippines and a number of the small South Pacific islands: viz Solomon Islands, Marshall, Mariana, and Caroline Islands, Fiji, New Caledonia, New Hebrides. (Table 46).

90% of all Indonesian shell exports are Trochidae, over 1 000 tonnes being exported annually (Table 47). Exports have fluctuated but slightly fewer were being exported annually at the end of the 1970s than at the beginning, mainly due to a decline in exports to European countries. Exports went mainly to Japan and Singapore in 1978.

Exports from the Solomon Islands were destined mainly for Japan; exports decreased between 1976 and 1978 (Table 48). Philippine exports of Trochidae decreased between 1970 and 1978; most were sent to Japan (Table 49).

The main importers of Trochus are Japan and Singapore (Table 50). Japanese imports come mainly from Indonesia and the South Pacific islands (Table 51).

Green snail shell (Turbo marmoratus)

This species is recorded separately only by Indonesia, the Solomon Islands and Papua New Guinea. Exports went mainly to Japan, Hong Kong, Singapore and West Germany (Tables 52, 53 and 54).

UNWORKED SHELLS-OTHER SPECIES .

S.Korea records imports of abalone shells. Imports increased from just over 1 000 tonnes in 1976 to nearly 2 000 tonnes in 1978, and 50% came from Mexico. Other major suppliers were the US, Australia and Japan (Table 55).

The Philippines recorded exports of Placuna placenta, the window pane oyster or capiz shell until 1972. Between 1970 and 1972 exports decreased drastically (Table 56).

India recorded trade in cowries and chanks (Turbinella pyrum) in 1976 and 1977 (Tables 57). Cowries were imported from the Maldives and were exported (domestic exports) to the US. Exports of chanks were lower in 1977 than in 1976; they were destined for Italy and other European countries and in 1977, for the US.

The Bahamas recorded imports and exports of conches in 1976 and 1977. In 1976, 3 535 conch shells were imported from the

US and in 1977, 710. Exports were not recorded in 1976 but in 1977 13 575 were exported of which 11 180 went to Italy and 2 395 to the US (Bahamas Foreign Trade Statistics).

WORKED SHELLS

The only worked shell recorded regularly in trade statistics is mother-of-pearl. Quantities recorded under the tariff heading for worked materials include other materials which may be part of the items concerned and so the weights give only a rough estimate of the actual quantities involved.

The main exporters of worked mother-of-pearl are the Philippines, Taiwan, South Korea, Japan and Thailand (Tables 58 a and b). The Far East has traditionally been the centre of the carving industry for a number of wildlife products including coral, shells, ivory and tortoiseshell. In Europe, Italy and West Germany are the only countries which record substantial exports; Italy is famous for its carved cameos and corals.

Trade statistics show the main importers of worked shell, including articles made of shell, to be the US, Japan and Europe particularly France, West Germany, Spain, Italy and the UK. (Tables 59 a and b).

Mainland China is also an important exporter; a number of countries imported from there, and estimated exports for Mainland China in 1976 were 20 517 kg.

Exporting Countries

The Philippines record worked shell and articles made

of shell under a number of headings which include handbags, lampshades, buttons, capiz shell, mother-of-pearl and 'other shells' (Table 60). The main destinations ^{between 1976 and 1978} were the US, Hawaii, Japan, Australia and Europe but exports went to many other countries as well. Taiwan also exported a variety of types of worked mother-of-pearl (Table 61) which went to many countries.

Exports from South Korea went mainly to Japan and the US, although exports to these two countries decreased between 1976 and 1978; exports to Hong Kong and Middle Eastern countries increased however (Table 62). Japanese exports increased between 1976 and 1978 and went mainly to Spain and the US (Table 63). Exports from Thailand also increased (Table 58a). Hong Kong recorded exports and re-exports of pearl buttons; both increased rapidly between 1976 and 1978 particularly to Australia and Taiwan (Table 64 a and b).

Importing countries

Most Japanese imports of worked mother-of-pearl came from South Korea, the Philippines and Mainland China (Table 65a). Large quantities of mother-of-pearl for buttons were imported from South Korea (Table 65b). Imports into France, West Germany and the UK of worked mother-of-pearl came primarily from the Philippines (Table 66 a, b and c). Spanish and Italian imports came from a number of countries of which Japan was the main source (Tables 66d and e).

US imports of worked shell were recorded under two tariff headings: "Cut cameos and coral for jewelry" and "Articles of shell". Imports of the former increased dramatically in the 1970s and are discussed in Wells (1980). Values of annual imports

of articles made from shells also increased rapidly between 1972 and 1976, mainly as a result of increased imports from the Philippines, which is the major supplier (Table 67 and Fig. 5). The US imports shell or pearl buttons but statistics were only obtained for 1969 and 1975; in 1969 the Philippines was the main supplier and in 1975, Japan (Table 68).

Imports of shell buttons into Hong Kong increased three-fold between 1976 and 1978. Over 75% came from Japan (Table 69).

REVIEW OF LITERATURE AND DISCUSSION

Countries involved

The trade statistics analysed in the preceding sections suggest that the demand for tropical sea shells and articles made from them increased throughout the 1970s. The US and Japan, the two major consumers of ornamental shells have shown marked increases in imports of unworked shells, as has South Korea. The US in particular has shown a huge increase in imports of worked shell. The extent to which these statistics refer to ornamental tropical shells can be gauged from information available on the retail and wholesale end of the trade.

Abbott (1980) carried out a detailed analysis of the shell trade in Florida, which has a greater number of shell dealers than any other state in the US. He found that 85% of the wholesalers obtained their shells in bulk from overseas, and according to the dealers, the main countries of origin (in descending order of importance) are the Philippines, Mexico, Haiti, India, Taiwan,

Japan and East Africa, with fewest coming from domestic waters and other countries. The trade statistics confirm this (ignoring European sources which almost certainly provide shells for industrial purposes).

Abbott identified some 300 species on sale in Florida, with another 4 700 species likely to appear from time to time. The most popular selling species are: the Pink Conch (Strombus gigas), the tiger cowrie (Cypraea tigris), the Pink Mexican murex (Phyllonotus erythrostomus), the Chambered Nautilus (Nautilus pompilius), scallops, large clam shells (Hippopus and Tridacna) and large showy gastropods such as Voluta, Tonna, Syrinx and Pleuroploca. Other studies (e.g. Evans et al., 1977) have also shown that the most popular species are the large colourful ones found on tropical reefs, which explains the major trade which has developed with tropical countries such as the Philippines, Mexico and Haiti.

Mexico has recently become one of the main suppliers of shells, especially for the US, Japan and South Korea. FAO statistics show that it was a major producer of shells other than mother-of-pearl between 1974 and 1977 (Table 70c). (FAO statistics are included for comparison but their figures clearly do not include all the countries involved in shell exploitation). It was also shown to have exported large numbers of abalone shells to South Korea (see Table 55), which may be a by-product of the abalone meat industry. There is little information on the areas in Mexico where shells are collected, but the increase in exports may be due to stepped up off-shore fishing for Murex, Oliva, Strombus and abalone (Abbott, 1980).

In the mid 1970s the Philippines was easily the major supplier and it is still one of the main exporters. Philippine collectors tend to collect anything and sell in bulk without discriminating between species (Webster, 1977 in litt.). Haiti's large export trade is due to organised wholesalers on La Gonave island, where labour is cheap; the meat is used for food (Abbott, 1980).

There is clear evidence that exports of shells from India are increasing rapidly. Recently some of its off-shore beds have been exploited for the first time (Abbott, 1980). Large specimens of ornamental shells were being collected round Rameshwaram and the Andaman and Nicobar islands at the beginning of the 1970s (Durve, 1975). Currently large quantities are being collected along the south Indian coast, especially off Tuticorin, south of Madras and Rameshwaran. Nearly two dozen species are involved and they are exported through Bombay, (Kannan 1980 in litt.).

There is little information on the export trade from East Africa although both trade statistics and FAO figures confirm that Kenya and Tanzania are important producers. Studies on the souvenir shell trade within Kenya showed that the main collecting areas are now the more inaccessible areas on the north and south coasts, such as Lamu and Shimon; popular species are relatively rare near the tourist resorts, probably as a result of over-collecting. At least one firm is known to export shells from Mombasa, (the Naushad Trading Co). including Cassis rufa destined for the cameo industry in Italy (Evans et al., 1974; Wells, 1978).

Ornamental shells are generally sold in seaside curio and

and souvenir shops, which in the past probably sold souvenirs decorated with local shells. In many places however, colourful local species may now be hard to find, especially in tourist resorts bordered by coral reefs such as Florida, Hawaii and the Caribbean islands, and because of their relative rarity^{key}, may also be more expensive than exotic shells imported in bulk. In Hawaii, where tourism has increased rapidly since 1972, nearly 60% of several hundred shops in Lahaina on Maui had some trade in molluscs in 1977, most of which were imported from all over the Indo-Pacific, especially from the Philippines and India (Mills, 1977). The Philippines exported over 115 tonnes of shells to Hawaii in 1978 (Table 11). The largest wholesale enterprise for shells in Hawaii in 1976 was 'Exotic Shells' and most of their stock was imported from countries including Taiwan and Mauritius. Shells were imported by the crate load in such quantities that the owner, Bremont, had little idea of the size of his stock or the species involved at any one time (Taylor, 1976).

In the UK in 1977, Leslie Sarogny-Frye was importing 10 tonnes of assorted corals and shells from the Philippines every two months, his main sales being to hotels and sea side gift shops (Anon, 1977). In 1978 Barry Lonsdale of Tropical Sea Shells in Rochdale in the UK was selling about 3 tonnes of shells a week, imported from the Philippines, East Africa and the Seychelles (Anon, 1978).

Mother-of-Pearl

Mother-of-pearl is one of the few types of shell for which fairly detailed trade statistics are available. Four species are commonly fished for their nacre, and provide the best mother-of-pearl.

<u>Pinctada margaritifera</u>	Black-lip pearl shell
<u>Pinctada maxima</u>	Gold-lip pearl shell
<u>Tectus niloticus</u>	Trochus or top shell
<u>Turbo marmoratus</u>	Green snail or turban shell

A number of other Pinctada species, abalone shells, chanks and freshwater mussels are also used. Mother-of pearl has been used for centuries for decorative inlay work, buttons and jewelry as it is hard and can be cut precisely and polished to a rich sheen. The pearl button industry reached a peak in the late 19th century when the UK alone imported at least 2 000 tons of pearl shell a year (Saul, 1974). Pearl buttons have to be made by hand and with the escalation of labour costs in Europe and the US, and the development of the plastics industry the trade declined (Saul, 1974: Travis, 1959). There now appears to be a revival of interest in mother-of-pearl as a fashionable material for buttons and jewelry, probably as part of the general trend away from plastics and the return to the use of natural products in the developed countries; the tortoiseshell trade has undergone a similar revival (Mack, Duplaix and Wells, 1980). Export statistics show that most manufactured articles come from the Far East where labour is still cheap.

Pinctada margaritifera, which purportedly produces the world's finest pearls, was formerly not in demand for its nacre (Major, 1974). Japan now imports large quantities of this species from the Philippines and Indonesia. In 1931 it was common and widely distributed in the Sulu Archipelago, and the Philippines exported about 20 000 kg of shell a year (Talavera, 1931); in 1979 Japan imported 209 805 kg a year -(Table 30a.)

P. maxima has always been in demand for its shell, particularly for the button industry. Japanese imports in 1979 were coming mainly from the Philippines and Indonesia although Australia used to be a major supplier. In 1931 this species was reported to be very abundant in the Philippines and almost the whole of the Sulu Archipelago was said to be one extensive pearling bank, 35 000 km². The growth rate of this species is rapid, it is sexually mature in two years, and most valuable when 3-4 years old and so it may be able to support a fairly large take. The Philippines exported just over 200 000 kg a year in 1927 and 1928 to the US, Europe, Hong Kong, Japan and the British East Indies (Talavera, 1931). In 1979 Japan imported 169 046 kg of this species from the Philippines.

FAO records catches and landings of Pinctada spp. (Table 70a). Between 1974 and 1977, highest catches were recorded for Australia. Japan and Fiji were also recorded but not the Philippines or Indonesia.

Traditionally there has been an extensive pearl oyster fishery in the Red Sea (Harrison Matthews, 1975). Few countries have recently recorded imports specifically of unworked pearl shell from this area (39 000 kg were imported from the Sudan in 1978 by Spain), but the Sudan, Somalia, Saudi Arabia and North and South Yemen are known to be involved in the coral and shell trade (see Table 1). Between 1960 and 1963 the US regularly imported pearl shells from Aden and Arabia (Table 45).

Tectus niloticus is the largest of the top shells

and is most in demand for its mother-of-pearl although other top shells such as T. maximus may also be used (Talavera 1931, Saul 1974). The main exporters of Tectus^(Tectus) appear to be Indonesia and the South Pacific islands (Table 46), (according to FAO statistics highest catches are obtained in the Solomon Islands and Fiji (Table 70 b)). According to Dance (1976) the principal Tectus^(Tectus) beds are off the coasts of New Caledonia and Queensland and amongst the Andaman and Nicobar Islands. The trade statistics suggest that exports from Indonesia, the Philippines and the Solomon Islands are declining. Unlike pearl oysters, this species never occurs in large numbers over a limited area, but is usually found scattered singly near the outer edge of coral reefs.

Over fishing of this species has been recorded a number of times as the following figures giving the tonnage fished legally may indicate (Dance, 1976).

<u>Queensland</u>		<u>New Caledonia</u>		<u>Andamans and Nicobar</u>	
1916	1 048	1913	1 004	1930	450
1922	265	1930	180	1935	50

(figures in tons)

According to Dance (op. cit), approximately 4 000 specimens comprise a ton and it takes more than 3 years to grow to a marketable size. Dance believed that had the plastics industry not replaced the need for this species it would have been on the verge of extinction.

In Papua New Guinea legislation had to be introduced to control fishing for Tectus niloticus. At the beginning of this century production dropped substantially from 1 000 tonnes in 1913 to 358 tonnes in 1928. During the Second World War, fishing stopped and the stocks had a chance to recuperate. 800

tonnes were taken in 1954 when fishing was resumed, but by 1956 the catch had already decreased to 402 tonnes. A moratorium was introduced for a year and since then commercial fishing has been permitted, provided a minimum size limit of 10 cm. diameter is adhered to and fishing zones are rotated (Barletta, 1976). In 1978 Papua New Guinea was about the fourth largest exporter of Tectus. In 1927 and 1928, the Philippines exported about 100 000 kg annually to China, Japan and the British East Indies; in 1978 the Philippines exported nearly 127 000 kg mainly to Japan, Spain and Italy (see Table 49). It is not clear what controls exist currently in this and other exporting countries to prevent over exploitation.

Green snail shells Turbo marmoratus were once used as festive drinking cups in Scandinavian countries, and they have also been used for buttons and other decorations. The surface can be treated and polished to reveal a greenish pearly nacre (Saul, 1974). This species is found at greater depths than other pearl shells, on the edges of reefs and it is usually collected by skin divers. Currently the Solomon Islands and Papua New Guinea are the major suppliers. In 1931 the Philippines exported 11 666 kg (Talavera, 1931) and in 1930 it was being fished off the Seychelles and Chagos (Travis, 1959). FAO recorded production of 400 tonnes a year between 1974 and 1977 in Sabah.

The mother-of-pearl trade is subject to the influence of trade in mother-of-pearl from fresh water molluscs (Unionidae) which in the US have provided a major source of mother-of-pearl since the last century. Pearl buttons began to be manufactured from them on a commercial scale in 1891, but by early this century depletion of the mussel beds was apparent, and

production declined. During and after the Second World War many of the commercial beds underwent a mild recovery as a result of the low level of exploitation along with attempts to clean up the rivers and decrease pollution.

In the 1950s the Japanese turned to North America for supplies of freshwater mussels as these are crushed and used to seed cultured pearl oysters. Previously they had been able to obtain supplies from the Yangtse River in China. Since the export trade with Japan has been opened up, North American rivers have been successively depleted as boats move on to new ones having exhausted others. In 1971 it was stated that it seemed unlikely that the industry could continue for another decade at the same rate of exploitation (Stansbery, 1971), and a symposium on rare and endangered molluscs in the US recommended that trade should be restricted to licensed collectors (Jorgensen and Sharp, 1971). However, according to FAO statistics an average of 1 436 tonnes were caught annually between 1974 and 1977. Trade statistics show that exports of shells to Japan from the US are still high, although lower than in the 1960s. A number of the rare Unionidae species are now listed on the US Endangered Species Act and are on Appendix I&II of CITES (the Convention on International Trade in Endangered Species of Fauna and Flora). Clamming is forbidden in some areas to allow stocks to build up and some species are protected by state as well as federal laws (Fitzpatrick, 1963) but detailed up to date information on current legislation has not been obtained.

Other species

Capiz shell or the window pane oyster (Placuna placenta) has been used in the Far East, especially in China, for many years as glass for windows, as its valves are thin and translucent. In the Philippines they have been used for the same purpose during the past 100 years. The pearls produced by this species are small and soft and are used only for medicinal purposes. The shells are found in large beds which may yield substantial crops regularly. They are collected by wading and many of the shells taken are in fact dead. They need a muddy or sandy substrate and are most successful in shallow water, although they may occur as deep as 40 m.

In 1931 the shells were still used in Philippine houses, but were increasingly used for shell crafts which is their main use now. Artificial cultivation was being successfully carried out in 1931, in combination with oyster farming, and since only large shells were of real value it was thought that wild populations were unlikely to be fished out. Manufactured articles were exported to Europe, China, the US, Hong Kong and the British and Dutch East Indies, and it was presumed that the export trade would continue. Raw shells were also exported in small quantities to the US and Hong Kong: 552 kg in 1927, 612 kg in 1928 and exports increased three-fold in 1929 (Talavera, 1931).

At the beginning of the 1970s unworked capiz shell was still being exported from the Philippines but there was a big drop in exports in 1972 and subsequently exports were not recorded.

An apparently unknown ecological disaster may have caused the failure of the beds (Kline, 1977). Worked capiz shells are still exported in large quantities however, and capiz shell articles from the Philippines can be seen in gift shops and department stores in the UK used in lampshades, boxes and aolian harps (pers. obs). A sizeable fishery for capiz shells existed in India along the Bombay and Goa coasts (Durve, 1975).

India recorded exports of cowries (Cypraea) and chanks (Turbinella pyrum) under separate tariff headings. An average tiger cowry (C. tigris), which is one of the most popular species, probably weighs no more than 100 gms; Indian exports in 1977 therefore represented well over 45 million specimens, and probably many more as other species such as the tiny ring and money cowries (C. moneta and C. annulus) were probably included in these export figures. A dealer in the UK supplied three quarters of a million cowries to a firm in 1977 which was marketing a game which required cowries, (Anon, 1977). Cowries are now frequently carved, or sliced and turned into napkin rings, or used in jewelry; money cowry necklaces are sold in most major cities of the world.

The Sacred Chank has a special holy significance in India and has been collected for centuries for use as trumpets and libation vessels in temples, and they are also used for buttons and bangles. Chank beds are found on the west coast, in the Gulf of Kutch and the Arabian Sea, ^{and} on the east coast. The most productive beds are mainly in the Gulf of Mannar near Tuticorin, Kilakari and in the Palk Bay area. Durve (1975) recommended that they should be carefully monitored to ensure that depletion does not occur

through over fishing. A survey of the chank has also been carried out in Sri Lanka (Abbott, 1980).

The valves of the Giant clam (Tridacna and Hippopus) have been much in demand and have been used as fonts in churches, salad bowls in restaurants and wash basins in hotels among other things. One shell shop in London has them in stock but a pair may cost £300. The main threat to clams is not collection for the shell, but the Taiwanese who fish them for the meat of the adductor muscles, and throw the valves away. Considerable depletion has occurred in Australian waters but a 200 mile economic zone has been enforced and Taiwanese fishing vessels are no longer seen (Pearson, 1977).

The Pearly Nautilus (Nautilus pompilius) has been collected in large numbers although it is a deep sea rather than a reef species. Their use is very varied and apart from being used whole as ornaments (usually sectioned), 800 pearly nautilus were used in the chandelier of the Senate chambers in the State Capitol in the US (Taylor, 1976); currently there is a vogue for handbags inlaid with pieces of pearly nautilus, imported from the Philippines, and Abbott (1980) recommends that a survey should be carried out to see if this species is being overfished in Philippine waters. A number of scientists are studying Nautilus at present and so such research would not be too difficult to implement.

"Rare" shells

Certain species have been greatly sought after over the centuries for their rarity alone. These generally command very high prices and are collectors items. In many cases their rarity is due to the fact that they are deep water species and in the past

were difficult to obtain. With the development of new techniques of deep sea fishing and diving, such species are becoming more common, and their value will naturally drop as more come onto the market. However, there are fears that populations could be damaged, as demand is still high.

A business has recently started in London under the name of Rare Shell Investment Services which advises people on investing in rare shells (TRAFFIC (International) files). Their brochure maintains that values have increased with remarkable consistency and that shells are a better investment than, for example, carpets, firearms or Chinese ceramics, as 'there is little that can go wrong when investing in a disappearing rare commodity'. Investing in rare shells is particularly popular in the US and is becoming increasingly so in the Middle East. In 1980 it was recommended that investment in the following species would be profitable: Lambis violacea (Mauritius), Harpa costata (Mauritius), Cypraea nivosa (Indian ocean) and some of the Australian volutes (Lee, Rare Shell Investment Services, in litt., 1980). These species are listed among the fifty rarest shells in the world (Dance, 1969). The Australian volutes could be threatened by over collection (Taylor, 1980 in litt.) and although many specimens of H. costata are now in collections large fine specimens are still rare (Dance, 1969).

The Shell Collector magazine in Florida noted that deep water gill nets of Philippine fishermen had now made a number of rare species available such as Conus gloriamaris (Glory of the Sea - once thought to be extinct, but over 100 specimens now known Dance, 1969), C. dusaveli (Mauritius, but according to Dance (1969) only one specimen ever found) and Augeria sphaerula. An article

in the 'Carfell Philippine Shell News' (Anon, 1979) mentioned that high monetary returns for rare shells have encouraged fishermen to give up fishing for shelling. A fine nylon net is used, about 1m wide and 150m long, which is cast to lie 60-120 fathoms or deeper overnight and then pulled in. Obtaining rare shells is still a difficult business, so the fact that it is more worthwhile than fishing further emphasizes a big boom in collecting.

Legislation

Many countries have legislation to control fishing for edible molluscs. In the US all coastal states have some form of control limiting size, quantities taken or times of the year that fishing may be carried out (Abbott, 1980), and many European countries have similar controls (Barletta, 1976). In many cases such legislation was drawn up only after it was realised that local depletion of populations was taking place.

A number of countries now indirectly protect molluscs through the establishment of marine parks, within the boundaries of which collection of marine organisms is usually forbidden. Such parks exist off the coasts of Australia, Florida, Kenya, Sri Lanka and many other countries (SS Coral Reef Group, 1979). These areas provide protected populations from which migration may occur to repopulate depleted areas.

Relatively few countries specifically control trade in ornamental shells. Japan and Australia have apparently recently implemented restrictions on commercial shell collecting (Abbott, 1980). In Kenya export of shells was previously permitted provided a license or permit was obtained. This legislation was poorly enforced though and shells could be freely taken out of the country

(Wells, 1978). In 1979 however, a complete ban on export was introduced (Anon, 1979); the increase in exports in 1978 (see Table 20) may have been due to traders getting rid of their stocks in anticipation of the ban. However apparently the legislation is confusing and poorly understood and shells are probably still leaving the country (Burton, 1980 pers. comm.)

In Papua New Guinea commercial shell collecting is controlled by the government. Collectors are instructed as to which species will sell well, and how they should be packaged to avoid damage and consequent wastage, and collecting areas are changed at regularly intervals (Anon, 1977a). No information is available on the effectiveness of this system.

A few countries have legislation for particular species. In Bermuda collection of the following species is prohibited: Queen and harbour conches (Strombus gigas), Bermuda cone, Bermuda and Calico scallops (Acquiptecten gibous), Atlantic pearl oyster, netted olive (Oliva reticularis) and all helmet and bonnet shells (Cassidae) (Anon, 1976). There has also been a curb on the export of conch shells from the Bahamas (Anon, 1977) although they were still being exported in 1977 (see p.14). This curb has forced dealers to find new suppliers in Hawaii (Anon, 1977). The export of the Golden cowry (Cypraea aurantium), one of the most sought after and valuable rare shells, is forbidden from Fiji (Platt, 1949). Florida limits the collection of the Queen conch (Strombus gigas) to 10 per person per day to prevent commercial exploitation (Abbott, 1980). In 1971, legislation was introduced in South Australia to control exploitation of Cypraea thesities since populations had been considerably

reduced by collectors (Coleman, 1972).

Conclusion

A great many observers including biologists, amateur shell collectors and conservationists are concerned about the possible decline of molluscs particularly on coral reefs and the damage which may occur through careless methods of collection, but further studies must be carried out to determine quantitatively the effect that collecting on a commercial level has on shell populations. It is unlikely that human exploitation could lead to the extinction of any one species of marine mollusc in view of their life history. Most marine molluscs have a huge reproductive capacity and produce planktonic larvae which may ensure wide dispersal, and account for the fact that many of the species in the ornamental shell trade have very wide distributions throughout the Indo-Pacific. Furthermore, for many species, it would be very difficult to find and collect every single specimen in a given area. Abbott (1980) points out that habitat disturbance, pollution and dredging are just as damaging as over collecting. A study by Rao in 1937 (Abbott, 1980) showed that the living population of Trochus in the Andaman Sea could number 300 million specimens; if this is correct, and Trochus reaches maturity and a collectible size in 4-5 years, it might be feasible to collect 10-20 million specimens a year.

However, in a number of cases there is evidence that over collection has led to local depletion and on occasions to economic , if not biological, extinction. In the Caribbean and off the coast of Florida a number of species are now uncommon through over collecting including the Pink Conch

(Strombas gigas), the Queen Helmet (Cassis madagascariensis), the Florida Horse Conch (Pleuroploca gigantea), Triton's Trumpet in Haiti (Charonia variegata), the Angel Wing (Cyrtoplenra costata), the Flamingo Tongue (Cyphoma gibbosum), and the King's Crown (Melongena corona), although they cannot be considered as endangered (Abbott, 1980). A number of dealers have mentioned that they are making money less easily than previously (Abbott, 1980) and a dealer in the UK was losing deals as a result of Philippine traders sending poorer quality shells that he had paid for (Anon, 1977). However demand for shells seems to be as high as ever, and with the increase in controls on coral exploitation, a number of dealers are expanding the shell side of their businesses to counteract the anticipated decline in the coral business (CNA, 1979).

Data from a preliminary study to look at the effect of shell collecting on mollusc populations in Kenya suggests that shell populations in unprotected areas may have a smaller mean length and less variation in size than those ^{which are protected} within marine parks (McClanahan and Muthigo, 1979). Since experience has shown that overcollection can have serious effects on edible mollusc populations, it is to be expected that the same may apply to the ornamental species.

At a preliminary meeting of the proposed Indian Ocean Alliance for Conservation in the Seychelles it was recommended that the problem of sea shell collecting should be considered at a national level and that protected areas should be established to provide breeding nuclei of marine molluscs (Anon, 1980). The Pacific Science Association at the XIV Congress in Khabarovsk

(USSR) in 1979 went further and included in their second resolution an appeal to all nations to stop the international trade in reef corals and molluscs for ornamental purposes. Barletta (1976) recommended that trade in the species used for the cameo industry (Cassia madagascarensis, Cypraea cassis rufa, and Stombus gigas) should be restricted by law.

Molluscs are an important economic resource in many countries, and a well organised ornamental shell trade could provide much needed income in developing countries. As pointed out by Abbott (1980) trade data can tell one little about the extent of over exploitation unless the ecology of the species is understood. Field studies urgently need to be carried out on species heavily involved in the trade to determine optimum yields or conservation measures that should be taken. In the Philippines such a programme is being undertaken for corals which are being collected for ornamental purposes, and since this country is one of the main shell exporters the programme should be extended to include molluscs as well. Abbott (1980) suggests a survey of the Pearly Nautilus should be carried out in these waters to determine if it is being overfished. Data is also needed on the extent to which both the meat and shell of different species are utilised; in a number of countries the meat of Cassidae, Stomidae and abalone is eaten and the shells exported but there are possibly a number of other species which could be used in this way.
